RNN

$x^{(t)}$ represents the t^{th} element in the time series.

Notation :

X : A collection of time-series : $\text{shape} = (n_s, n_{ts}, n_f)$

Samples # time-series in each Sample # features.

Y : A collection of labels : $\text{shape} = (n_s, n_{ts})$

length of y outputs

n n - Circle around

$n_{tsy} : 1 \rightarrow \text{Single output}$ length of y outputs

$$n_{tsy} = n_{ts}$$

Time \rightarrow

$X^{(i) \langle t \rangle}$: t^{th} instance in $X^{(i)}$.

Mathematical representation of RNN:

$$a^{(t)} = g_a(W_a a^{(t-1)} + U_a X^{(t)} + b_a) \quad g_a: \text{tanh/Relu}$$

$$y^{(t)} = g_y(W_y a^{(t-1)} + U_y X^{(t)} + b_y) \quad g_y: \text{Sigmoid} \dots$$

GRU
&
LSTM

LSTM

Issue with RNN: Vanishing/Exploding Gradient

Solution: Keep a memory

Memory:

* Store some info $\rightarrow \Gamma_s$

* Forget " " $\rightarrow \Gamma_f$

* Retrieve " " $\rightarrow \Gamma_r$ output

LSTM

$$C^{(t)} = \tanh(W_m a^{(t-1)} + U_m X^{(t)} + b_m)$$

$$\Gamma_s = \text{Sig}(W_s a^{(t-1)} + U_s X^{(t)} + b_s)$$

$$\Gamma_f = \text{Sig}(W_f a^{(t-1)} + U_f X^{(t)} + b_f)$$

$$C^{(t)} = \Gamma_s C^{(t)} + \Gamma_f C^{(t-1)}$$

$$\Gamma_r = \text{Sig}(W_r a^{(t-1)} + U_r X^{(t)} + b_r)$$

$$a^{(t)} = \Gamma_r C^{(t)}$$

For GRU

$$\begin{cases} \Gamma_f = 1 - \Gamma_s \\ \Gamma_r = 1 \end{cases}$$

There's some additional Γ_I to indicate the impact of the memory.

$$C^{(t)} = \tanh(W_m \Gamma_I a^{(t-1)} + U_m X^{(t)} + b_m)$$

Intuition

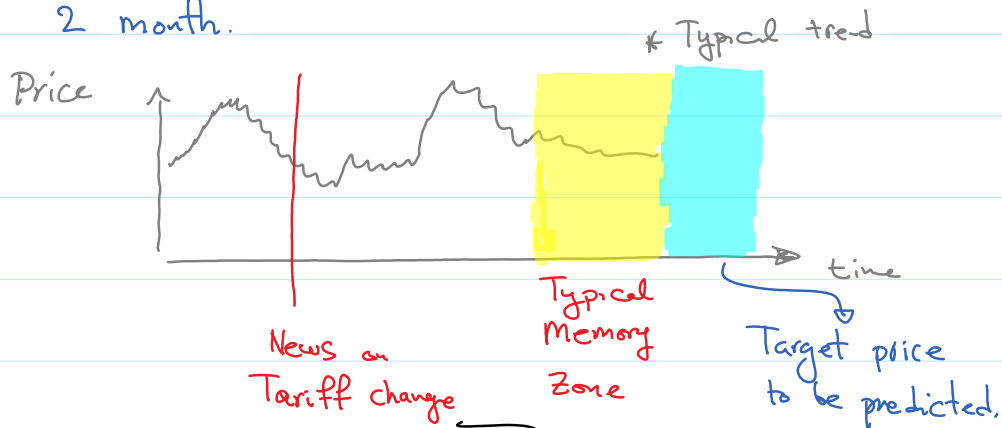

$a^{(t)}$ only provides a short memory.

$C^{(t)}$ is to extend this SM over a longer time.

Consider the price of some goods (some metal, etc.)

There's the typical input, daily price that helps predicting the price of tomorrow.

Then there's a news on tariff change in 2 month.

With a normal RNN, does not fall in the memory window and is neglected.

But with LSTM, here's what could happen (Naively):

This way the memory $C^{(t)}$ can provide a tool for keeping significant info over a longer range of time.
